Subject: Geotechnical Report
Arlington 360
8904, 9104, 9110, and 9116 Tveit Road
Arlington, Washington

Dear Mr. Huseby:

As requested, we conducted a geotechnical engineering study for the subject project. The attached report presents our findings and recommendations for the geotechnical aspects of project design and construction.

Our field exploration indicates the site is underlain by glacially deposited sediments composed of glacial till overlying advance outwash overlying pre-glacial deposits composed of lacustrine and fine-grained deposits. Perched groundwater seepage was observed at numerous depths within each of the distinct geologic formations above the lower fine-grained deposits.

In our opinion, there are no geotechnical conditions that would preclude the planned residential development. Residences can be supported on conventional spread footings bearing on competent native soils underlying the surface organic soils, on structural fill placed on the competent native soils. Floor slabs and pavements can be similarly supported.

Detailed recommendations addressing these issues and other geotechnical design considerations are presented in the attached report. We trust the information presented is sufficient for your current needs. If you have any questions or require additional information, please call.

Sincerely yours,
**TERRA ASSOCIATES, INC.**

## 1.0 PROJECT DESCRIPTION

The proposed project consists of developing the site with 670 single family residential building lots, 5 detention vaults, 2 detention ponds, 2 major roadways, and associated access and utilities. The development will be divided by existing critical areas and existing roadways. Based on the preliminary grading plans prepared by SolidGround dated November 7, 2025, grading to achieve building lot and roadway grades will consist of cuts and fills from 1 to 25 feet.

Site stormwater will be collected and directed to one of five detention vaults or one of two detention ponds. The detention vaults are located throughout the proposed development. The ponds are located along the roadway improvements in the north and central portions of the site.

We expect the single-family residences will be two- to three-story, wood-frame buildings with their main floor levels framed over a crawl space and attached garages constructed at grade. Foundation loads should be relatively light, in the range of 2 to 3 kips per foot for bearing walls and 25 to 50 kips for isolated columns.

The recommendations contained in the following sections of this report are preliminary and based on our understanding of the above design features. We should review design drawings as they become available to verify our recommendations have been properly interpreted and incorporated into project design and to amend or supplement our recommendations, if required.

## 2.0 SCOPE OF WORK

Our work was completed in accordance with our authorized proposal dated March 8, 2024. Accordingly, on April 22, 2024, through April 24, 2024, we explored subsurface conditions at the site within 9 test borings advanced with a hollow-stem auger to a maximum depth of approximately 50 feet below existing site grades. On April 7, 2025, through April 11, 2025, we supplement this data by drilling 6 additional wells to a maximum depth of approximately 90 feet below current site grades. Using the results of our field exploration and laboratory testing, along with existing subsurface data from a previous study of the property, analyses were undertaken to develop geotechnical recommendations for project design and construction. Specifically, this report addresses the following:

- Soil and groundwater conditions.
- Geologic hazards per the City of Arlington Municipal Code (AMC).
- Seismic design parameters per the 2021 International Building Code (IBC).
- Site preparation and grading.
- Relative slope stability.
- Excavations.

- Foundations.
- Slab-on-grade floors.
- Stormwater facilities.
- Infiltration feasibility.
- Drainage.
- Utilities.
- Pavements.

We have reviewed and incorporated existing subsurface data from a previous study of the property performed by Associated Earth Sciences, Inc. (AESI) which took place during the months of May, November, and December of 2023.

It should be noted that the recommendations outlined in this report regarding drainage are associated with soil strength, design earth pressures, erosion, and stability. Design and performance issues with respect to moisture as it relates to the structure environment are beyond Terra Associates' purview. A building envelope specialist or contractor should be consulted to address these issues, as needed.

## 3.0 SITE CONDITIONS

### 3.1 Surface

The proposed project site consists of 19 tax parcels totaling approximately 308 acres at, south of, and northeast of 8904, 9104, 9110, and 9116 Tveit Road in Arlington, Washington. The focus of subsurface exploration at this time has been the central 8 tax parcels totaling approximately 209 acres. The approximate site location is shown on Figure 1.

The northern parcels are currently developed near Tveit Road with four single-family residences and several outbuildings, along with associated access and utilities. The remainder of the area is undeveloped and covered with a moderate forest and associated understory with some cleared areas covered with grass and tall brush. Site topography generally consists of a moderate slope over an upland plateau which transitions to a steep slope in the northern portion of the site. Site grades descend from the south to the north with an overall vertical relief of approximately 350 feet. The steep slopes located in the northern and northwestern portions of the site generally descend over overall vertical reliefs of approximately 60 to 125 feet. There are also steep slopes within the development that descend to mapped drainage channels in the western portion of the site which flow to the north. The northeastern portion of the site similarly slopes towards a drainage channel located partially onsite to the northeast. Slopes descending towards the drainage channels typically show overall vertical reliefs of approximately 30 to 80 feet.

## 3.2 Soils

Based on the subsurface explorations and those completed by AESI, five primary geologic formations are understood to be underlying the site. Stratigraphy at the site typically consists of loose to very dense silty sand and sandy silt with varying gravel content (weathered and unweathered Vashon Lodgement Till) overlying medium dense to dense sand with varying silt and gravel content (Advance Outwash/Olympia Sand) overlying very stiff to hard silt deposits with varying sand content and interbedded medium dense to dense granular layers (Olympia Lacustrine Deposits) overlying very stiff to hard silt deposits (Olympia Fine-Grained Deposits).

Test Borings advanced along the northern steep slope performed by AESI showed landslide deposits composed of very loose to very dense disturbed sand and silt layers with varying silt, sand, and gravel contents as well as inclusions of organic material and topsoil. Some of the silt samples showed signs of fracturing and infilling. The landslide deposits were typically observed overlying the Olympia Lacustrine or Olympia Fine-Grained deposits and, in some cases, the Vashon Lodgement Till and Olympia Sand deposits.

Test Pits performed by AESI also indicated relatively limited and shallow deposits of loose to medium dense sand with silt to silty sand with varying gravel content (Recessional Outwash) up to approximately six feet in depth overlying the till deposits in the eastern and central portions of the site as well as along the northern portion of the site. Test Pit EP-24 in the northwestern portion of the site showed loose to medium dense and soft alluvial deposits composed of sand with silt to silty sand with varying gravel content and sandy silt to the termination of the test pit. Test Pit EP-25 showed approximately four feet of loose fill composed of fine silty sand overlying native recessional outwash deposits.

The thicknesses of the geologic units expressed above vary across the site. In general, Vashon Lodgement Till deposits extend to depths ranging from approximately 4 to 17 feet below existing site grades where the formation thins out towards the crest of the northern steep slope. The Advance Outwash/Olympia Sand deposits extend to depths ranging from approximately 18 to 58 feet below existing site grades. The Olympia Lacustrine deposits extend to depths ranging from approximately 43 to 93 feet below existing site grades. The landslide deposits extend to depths ranging from approximately 9 to 44 feet below existing site grades. Test Pits and Test Borings that encountered the Olympia Fine-Grained deposits terminated in the formation.

Based on a review of the Test Pit Logs prepared by AESI, the surficial organic horizon typically consists of approximately 3 to 12 inches of forest duff and organic topsoil.

Review of the *Geologic Map of the Arlington East Quadrangle, Snohomish County, Washington* by J.P. Minard (1985) shows the upland plateau of the property mapped as Vashon Till (Qvt). Advance Outwash (Qva) is mapped along the northern steep slopes and along the drainage channels. Transitional Beds (Qtb) is mapped along the base of the northern slope with Recessional Outwash (Qvrm and Qvra) mapped beyond the transitional beds to the northwestern edge of the property. It is our opinion that this mapping is generally consistent with the subsurface findings at the site, although we believe the Qtb description likely incorporates the Olympia Lacustrine and Fine-Grained deposits in the surface mapping.

The preceding discussion is intended to be a general review of the soil conditions encountered. For more detailed descriptions, please refer to the Test Boring Logs in Appendix A. Test Pit and Test Boring logs prepared by AESI may be found in Appendix B. The approximate locations of the subsurface explorations are shown on Figure 2.

## 3.3 Groundwater

Perched groundwater seepage was observed in many of the test borings and test pits ranging from depths of approximately 1.5 to 90 feet below existing grades. Typically, zones of limited perched seepage were observed within the till and outwash deposits within sand seams or above silt seams, respectively. Thicker zones of perched seepage were typically observed within the landslide deposits and lacustrine deposits with wet soils observed until the lower fine-grained deposits were encountered.

There were also limited thicknesses of perched seepage within these deposits periodically as well. Perched seepage was also encountered in the recessional outwash deposits above the lower till deposits. We did observe instances where the advance outwash formation was nearly fully inundated, such as at Test Borings B-101, B-102, B-103, and B-105 which were advanced near the crest of the northern slope. This typically indicates the formation acts as an aquifer near the slope. While the advance outwash formation is generally confined by the overlying till, test pit data obtained by AESI indicates the advance outwash aquifer is unconfined in the vicinity of Test Pits EP-13, EP-14, EP-16, and EP-17 located along the western portion of the northern slope and along the western drainage channel.

During reconnaissance of the site slopes performed by Terra Associates, Inc., we observed wet surface soils within the drainage channels and a point of seepage through exposed strata at the interface of the advance outwash and fine-grained formations (roughly elevation 240.0 feet) along what appeared to be an old cut road traversing from the south to north along the western portion of the northern slope. We also observed a point of seepage flowing from landslide deposits along the northern slope at an approximate elevation of 200.0 feet.

We expect groundwater levels and flow rates will fluctuate seasonally and will typically reach their highest levels during, and shortly following, the wet winter months (November through May). Given the time of year our field work was completed, and our experience with groundwater conditions in the area, the groundwater levels observed likely represent near seasonal high levels. To evaluate the seasonal weather influence, Test Borings B-101, B-104, B-107, B-109, B-201, B-202, and B-204, were converted to monitoring wells. The wells were instrumented on December 1, 2024, and on April 11, 2025. Monitoring wells installed by AESI were also instrumented. The instruments were downloaded on September 25, 2025. The groundwater levels are shown in Appendix C.

## 3.4 Geologic Hazards

Chapter 20.93.600.a of the City of Arlington Municipal Code (AMC) defines geologically hazardous areas as "areas susceptible to erosion, sliding, earthquakes, liquefaction, or other geological events. Geologically hazardous areas shall be classified based upon the history or existence of landslides, unstable soils, steep slopes, high erosion potential or seismic hazards." Discussions related to erosion, landslide, mine, and seismic hazards are presented as follows.

### *3.4.1 Erosion Hazard Areas*

Chapter 20.93.600.b.1 of the AMC defines erosion hazard areas as areas that are "defined by the USDA Soil Conservation Service, United States Geologic Survey, or by the Department of Ecology Coastal Zone Atlas. The following classes are high erosion hazard areas:

a) Class 3, class U (unstable) includes severe erosion hazards and rapid surface runoff areas;

b) Class 4, class UOS (unstable old slides) includes areas having severe limitations due to slope; and,

c) Class 5, class URS (unstable recent slides)."

The Soil Conservation Service (now called National Resources Conservation Service (NRCS)) shows mapped soils in the developable upslope and downslope portions of the site consisting of *Norma loam, Ragnar fine sandy loam, 0 to 8 percent slopes, and Tokul gravelly medial loam, 0 to 15 percent slopes*. The NRCS describes the erosion hazard of these materials as slightly to moderately susceptible to erosion when exposed which does not meet the above criteria defining a critical erosion hazard area. However, the soils located along the northern steep slope and drainage channels are mapped as *Patsik silt loam, 8 to 25 percent slopes, Tokul gravelly medial loam, 15 to 30 percent slopes, and Tokul-Winston gravelly loams, 25 to 65 percent slopes.* The erosion hazard of these materials is described as severely susceptible to erosion when exposed. Accordingly, the onsite steep slopes would be considered an erosion hazard area per the AMC.

Implementation of temporary and permanent Best Management Practices (BMPs) for preventing and controlling erosion will be required and will mitigate the erosion hazard. As a minimum, we recommend implementing the following erosion and sediment control BMPs prior to, during, and immediately following construction activities at the site:

***Prevention***

- Limit site clearing and grading activities to the relatively dry months (typically May through September).
- Limit disturbance to areas where construction is imminent.
- Locate temporary stockpiles of excavated soils no closer than ten feet from the crest of the slope.
- Provide temporary cover for cut slopes and soil stockpiles during periods of inactivity. Temporary cover may consist of durable plastic sheeting that is securely anchored to the ground or straw mulch.
- Establish permanent cover over exposed areas that will not be disturbed for a period of 30 days or more by seeding, in conjunction with a mulch cover or appropriate hydroseeding.

***Containment***

- Install a silt fence along sit margins and down slope of areas that will be disturbed. The silt fence should be in place before clearing and grading is initiated.
- Intercept surface water flow and route the flow away from the slope to a stabilized discharge point. Surface water must not discharge at the top or onto the face of the steep slope.
- Provide onsite sediment retention for collected runoff.

The contractor should perform daily review and maintenance of all erosion and sedimentation control measures at the site.

### *3.4.2 Landslide Hazard Areas*

Chapter 20.93.600.b.2 of the AMC defines landslide hazard areas as "areas subject to severe risk of landslide based on a combination of geologic, topographic and hydrologic factors. Some of these areas may be identified in the Department of Ecology Coastal Zone Atlas, or through site-specific criteria. Landslide hazard areas include any of the following:

a) Areas characterized by slopes greater than fifteen percent and impermeable soils (typically silt and clay) frequently interbedded with permeable granular soils (predominantly sand and gravel) or impermeable soils overlain with permeable soils or springs or groundwater seepage;

b) Any area that has exhibited movement during the Holocene epoch (from ten thousand years ago to present) or which is underlain by mass wastage debris of that epoch;

c) Any area potentially unstable due to rapid stream incision, stream bank erosion or undercutting by wave action;

d) Any area located on an alluvial fan presently subject to or potentially subject to inundation by debris flows or deposition of steam-transported sediments;

e) Any area with a slope of thirty-three percent or greater and with a vertical relief of ten or more feet except areas composed of consolidated rock;

f) Any area with slope defined by the United States Department of Agriculture Soil Conservation Service as having a severe limitation for building site development; and

g) Any shoreline designated or mapped as class U, UOS, or URS by the Department of Ecology Coastal Zone Atlas."

Review of mapped landslide areas on the Washington State Department of Natural Resources (DNR) Geologic Information Portal website shows the steep, north-facing slope located within the northern parcels mapped with scarps, flanks, landslide deposits, and fans. These mappings are assigned confidence levels ranging from low to high with an estimated relative age of greater than 150 years (Pre-historic). The test borings performed by AESI along the slope-face show relative densities of medium dense to very dense within the landslide deposits, with some surficial loose material, which would conform with the DNR's estimated age of the slide mass.

Maximum surface grades along the drainage channels in the western portion and along the northeastern portion of the site approach approximately 85 percent over a maximum vertical relief of up to approximately 80 feet. As described earlier, the underlying stratigraphy along these slopes consists of permeable outwash deposits overlying relatively impermeable fine-grained deposits. Subsurface exploration has shown the upper outwash formation to be water-bearing, and we observed one point of seepage at an exposed interface between the upper outwash formation and lower fine-grained deposits. Therefore, conditions 'a', 'b', and 'e' as described above are met. Per the AMC, the north-facing steep slope and the drainage channels located in the western and northeastern portions of the site meet the classification for landslide hazard area designation.

Additional analysis regarding the slopes has been completed for the project and can be found in Section 4.3 below.

### *3.4.3 Seismic Hazard Areas*

Chapter 20.93.600.b.4 of the AMC defines seismic hazard areas as "areas subject to severe risk of earthquake damage as a result of seismic induced settlement, shaking, slope failure or soil liquefaction. These conditions occur in areas underlain by cohesion less soils of low density usually in association with a shallow groundwater table."

A review of a map titled *Faults and Earthquakes in Washington State*, dated 2014 by Jessica L. Czajkowski and Jeffrey D. Bowman shows the site does not reside within any active fault zone. The nearest fault, the Darrington-Devils Mountain Fault, is located approximately 10 miles north of the site. Quaternary-age activity of the fault (rupture within the last two million years) is predicted to have occurred during the Pleistocene and possibly during the early Holocene, or roughly between 10,000 to 126,000 years ago. Accordingly, during a seismic event, the risk of ground rupture along a fault line at the site is low.

Liquefaction is a phenomenon where there is a reduction or complete loss of soil strength due to an increase in water pressure induced by vibrations. Liquefaction mainly affects geologically recent deposits of fine-grained sands underlying the groundwater table. Soils of this nature derive their strength from intergranular friction. The generated water pressure or pore pressure essentially separates the soil grains and eliminates this intergranular friction; thus, eliminating the soil's strength.

The predominant formations underlying the site consist of medium dense to very dense sand formations, medium dense to very dense till formations, and very stiff to hard cohesive fine-grained formations. The sand formations are relatively permeable and would allow dissipation of pore water pressures generated by a seismic event, thereby not significantly impacting the effective strength of the deposits. The risk for soil liquefaction occurring at the site in the till and lower fine-grained deposits is negligible due to the relative density of the soils and amount of cohesive material that would be sufficient to resist the cyclical loading of a seismic event.

In addition, the Washington DNR has mapped the site as having a low to very low potential for liquefaction on their Geologic Information Portal website. Therefore, it is our opinion that the risk for soil liquefaction to occur at this site and its associated impacts is low.

Section 4.3 of this report includes a discussion relating to the susceptibility of the steep slope to seismically induced landsliding.

### 3.5 Seismic Site Class

Based on the site soil conditions, DNR mapping, and our knowledge of the area geology, per the 2021 International Building Code (IBC), site class "D" should be used in structural design.

## 4.0 DISCUSSION AND RECOMMENDATIONS

### 4.1 General

Based on our study, there are no geotechnical conditions that would preclude the planned development. The proposed structures can be supported on conventional spread footings bearing on competent native soils underlying organic topsoil or on structural fill placed on a competent native soil subgrade. Floor slabs and pavements can be similarly supported.

The primary geotechnical concern for the site will be the presence of steep slopes and associated landslide hazards adjacent to and throughout the site. Preliminary site plans show a 345-foot slope buffer from the crest of the northeast steep slopes adjacent to the development and an 80-foot buffer from the crest of the northwest steep slopes adjacent to the development, along with an additional 15-foot building setback which will be necessary to mitigate potential damage to the development from potential slope movement.

Most of the native soils observed in the test pits and borings contain a sufficient amount of fines (silt- and clay-sized particles) that will make compaction as structural fill difficult when the soils are wet or dry of optimum. Accordingly, the ability to use these soils from site excavations as structural fill will depend on their moisture content and the prevailing weather conditions at the time of construction. If grading activities take place during extended periods of wet weather, the owner should be prepared to import free-draining granular material for use as structural fill and backfill. The relatively clean outwash deposits observed below the till deposits generally have a low percentage of soil fines and should be suitable for use as structural fill in most weather conditions.

Detailed recommendations regarding these issues and other geotechnical design considerations are provided in the following sections of this report. These recommendations should be incorporated into the final design drawings and construction specifications.

## 4.2 Site Preparation and Grading

To prepare the site for construction, all vegetation, organic surface soils, and other deleterious materials should be stripped from areas of new construction. We expect surface stripping depths to remove the organic surficial soils would generally be about 3 to 12 inches. Stripped vegetation debris should be removed from the site. Organic soils will not be suitable for use as structural fill but may be used for limited depths in nonstructural areas or for landscaping purposes. Abandoned utilities should be removed if existing within new building areas. Abandoned utility pipes that fall outside of new building areas can be left in place provided they are sealed to prevent intrusion of groundwater seepage and soil.

Some loose surficial soils were observed in test pits completed by AESI along the upper plateau within the till and recessional outwash deposits. The depth of the loose material is limited and should be scarified to a depth of 12 inches and compacted, meeting the requirements outlined below. The lateral extent of the loose soils should be determined in the field during grading procedures.

Once clearing and grubbing operations are complete, cut and fill operations to establish desired grades can be initiated. A representative of Terra Associates, Inc., should examine all bearing surfaces to verify that the conditions encountered are as anticipated and are suitable for placement of structural fill or direct support of building and pavement elements. Our representative may request proof rolling of exposed surfaces with a heavy rubber-tired vehicle to determine if any isolated soft and yielding areas are present. If unstable yielding areas are observed, they should be cut to firm bearing soil and filled to grade with structural fill. If the depth of excavation to remove unstable soils is excessive, use of geotextile fabric such as Mirafi 500X or equivalent in conjunction with structural fill can be considered in order to limit the depth of removal. In general, our experience has shown that a minimum of 18 inches of clean, granular structural fill over the geotextile fabric should establish a stable bearing surface.

Our study indicates most of the site soils contain a significant amount of fines (silt and clay-sized particles) that will make them difficult to compact as structural fill when too wet or too dry. Provided these soils are near optimum moisture when excavated, and are placed during dry weather conditions, we anticipate they will generally be suitable for direct use as structural fill.

Materials that are wet of optimum will require drying the soil by aeration during dry weather conditions or by using soil amendments such as lime or Portland cement to reduce and stabilize the soil's moisture content. If soil amendment products are used, additional Temporary Erosion and Sedimentation Control (TESC) BMPs will need to be implemented to mitigate potential impacts to stormwater runoff associated with possible elevated pH levels.

The relatively clean recessional outwash soils observed above the till deposits generally have a low percentage of soil fines and should be suitable for use as structural fill in most weather conditions. If grading activities are planned during the wet winter months, or if they extend into fall and winter, imported fill materials should consist of a granular soil that meets the following grading requirements:

| U.S. Sieve Size | Percent Passing |
|---|---|
| 3 inches | 100 |
| No. 4 | 75 maximum |
| No. 200 | 5 maximum* |

*Based on the 3/4-inch fraction.

Prior to use, Terra Associates, Inc. should examine and test all materials planned to be imported to the site for use as structural fill.

Structural fill should be placed in uniform loose layers not exceeding 12 inches and compacted to a minimum of 95 percent of the soil's maximum dry density, as determined by American Society for Testing and Materials (ASTM) Test Designation D-1557 (Modified Proctor). The moisture content of the soil at the time of compaction should be within two percent of its optimum, as determined by this ASTM standard. In nonstructural areas, the degree of compaction may be reduced to 90 percent.

## 4.3 Relative Slope Stability

Reconnaissance of the site's steep slopes showed several instances of leaning, pistoled-butted, and fallen trees. As described above, we observed a small number of seeps along the north-facing slope and wet surface soils within the drainage channels. However, the slopes are heavily vegetated with ferns, blackberries, and other forest understory, and support the growth of many upright small- to medium-sized trees, and we did not observe any evidence of new tension-cracking or new head scarps.

We have completed 19 slope stability analyses for the project site. Nine of the analyses were completed within the area of the landslide hazard in the northern portion of the site and ten of the analyses were completed outside of the landslide hazard area but still within a steep slope area. Our analyses were completed at locations designated as Cross Section A-A' through I-I' and AA-AA' through JJ-JJ' using the computer program Slide 2. The location of the cross sections is shown on attached Figure 2.

Our analysis considered both static and pseudostatic (seismic) conditions. A horizontal acceleration of 0.23g was used in the pseudostatic analysis to simulate slope performance under earthquake loading. This acceleration was determined following the FHWA-NHI-11-032 "Limit Equilibrium Pseudo Static Stability Analysis" procedure.

The results of our slope stability analysis, as shown by the lowest safety factors for each condition, are presented in the following table:

**Table 1 – Slope Stability Analysis Results**

**Cross Sections Located inside of the Landslide Hazard Area**

| Cross Section | Minimum Safety Factors | |
|---|---|---|
| | Existing Conditions | Post Construction |
| A-A' | 2.4 (Seismic FS = 1.2) | 2.0 (Seismic FS = 1.2) |
| B-B' | 1.0 (Seismic FS = 0.5) | 0.8* (Seismic FS = 0.3*) |
| C-C' | 0.8 (Seismic FS = 0.4) | 0.9* (Seismic FS = 0.5*) |
| D-D' | 1.0 (Seismic FS = 0.4) | 1.0* (Seismic FS = 0.6*) |
| E-E' | 0.7 (Seismic FS = 0.3) | 0.8* (Seismic FS = 0.5*) |
| G-G' | 1.5 (Seismic FS = 0.8) | 1.5 (Seismic FS = 1.0*) |
| H-H' | 1.3 (Seismic FS = 0.7) | 1.0* (Seismic FS = 0.6*) |
| I-I' | 1.3 (Seismic FS = 0.7) | 1.3* (Seismic FS = 0.8*) |

These cross sections are located along the north slope which is a landslide hazard area. The project does not propose to mitigate the hazard but will use buffers from the crest of the landslide hazard along with a 15-foot building setback to provide protection from the landslide hazard areas. Based on the results of the analysis we recommend a 345-foot buffer from the crest of the east landslide hazard area and an 80-foot buffer from the crest of the west landslide hazard area. These buffers have been incorporated into the civil plans.

The post construction slope stability analysis shows that with the appropriate buffers and building setback applied, the proposed development is between 20 feet and 309 feet from the nearest failure plane. By utilizing the larger buffer, it is our opinion that the proposed development can be completed as shown on the civil plans and maintain the necessary public safety requirements. The results of the analysis are included in Appendix D.

The project currently proposes to construct a road, sidewalk, and path within the east landslide hazard buffer. These proposed improvements are located approximately 250 feet from the crest of the landslide hazard area. They are approximately 20 feet from the nearest failure plane under the static condition and therefore meet the engineering standard factor of safety for the static condition. Roadway improvements are typically allowed within the landslide hazard buffers provided the analysis shows that the roadway will be accessible following a design level earthquake event.

In order to determine the potential impact of a design level earthquake on these proposed improvements we have completed a Newmark Analysis. For the analysis, we selected the Cape Mendocino 1992 earthquake that occurred on the southern end of the Cascadia subduction zone. The seismic record had a maximum ground acceleration of 0.385g and a magnitude of 7.1. The results of the Newmark Analysis indicate that if this section experiences a design level earthquake, the resulting lateral displacements would be approximately 0.5 inches or less in the area of the proposed improvements. The larger lateral displacements associated with the landslide hazard area are approximately 230 feet north of the proposed improvements and are not expected to impact the area.

In our opinion, this amount of lateral displacement would have little to no impact on the proposed development other than some tension cracking along the paved access road. Tension cracking of this magnitude will be easily traversable and would not impede vehicular movement along the road and therefore would not be considered a life safety issue. Utilities located within this area would be subject to some lateral displacement however, the amount of displacement is small enough to have a minimal impact on the utility.

Section A-A' is located on the east side of the project. The analysis of this section determined minimum factors of safety that meet the engineering standards of 1.5 for static and 1.1 for seismic. Therefore, it is our opinion that the proposed development can be constructed as shown.

**Table 2 – Slope Stability Analysis Results**

**Cross Sections Located outside of the Landslide Hazard Area**

| Cross Section | Minimum Safety Factors | |
|---|---|---|
| | **Existing Conditions** | **Post Construction** |
| F-F' | 1.5<br>(Seismic FS = 1.0*) | 1.7<br>(Seismic FS = 1.1) |
| AA-AA' | 2.0<br>(Seismic FS = 1.3) | 1.9<br>(Seismic FS = 1.2) |

| Cross Section | Minimum Safety Factors | |
|---|---|---|
| | **Existing Conditions** | **Post Construction** |
| II-II' | 1.7<br>(Seismic FS = 1.1) | 1.7<br>(Seismic FS = 1.1) |
| JJ-JJ' | 2.0<br>(Seismic FS = 1.2) | 2.0<br>(Seismic FS = 1.2) |

The results of our analyses indicate the site slopes are generally stable with respect to deep-seated movement under static conditions with the exception of Cross Section GG-GG'. The results of the analysis are included in Appendix E.

Section GG-GG' is located on along the proposed roadway improvements at the north end of the project. Potential failure surfaces associated with factors of safety below 1.5, which is the minimum safety factor considered acceptable for stable slopes under static conditions by local geotechnical engineering practice, extend about four feet behind the apparent steep slope crest. Pseudostatic analysis of the existing slope on Section GG-GG' indicates the slope would fail during a severe seismic event with potential failure surfaces associated with factors of safety below 1.1, which is the minimum safety factor considered acceptable for stable slopes under pseudostatic conditions by local geotechnical engineering practice, extending about 30 feet behind the apparent steep slope crest. Therefore, it is our opinion that an appropriate buffer of 35 feet will adequately mitigate potential steep slope hazards at this location.

Analyses of slope section HH-HH' indicate adequate factors of safety exist for the existing slopes and the proposed development under static conditions but not for pseudostatic conditions.

At Section HH-HH', potential failure surfaces associated with safety factors below the acceptable minimum value of 1.1 terminate at the apparent slope crest of the existing slope and extend about 23 feet beyond the apparent slope crest for the proposed development. In our opinion, establishing a minimum buffer of 30 feet between the existing slope crest and any proposed development, including lot fills, would adequately mitigate potential steep slope hazards at this location.

Based on our understanding of the planned site development, the results of our stability analysis, our site observations, and provided the recommendations contained in this report are followed, it is our opinion that the following table should be used to establish suitable buffers that will adequately mitigate geologic hazards associated with the steep slopes outside of the landslide hazard areas.

| SITE IMPROVEMENTS | BUFFER (FEET) |
|---|---|
| Building Lots 621, 652 – 660 | 15 |
| Detention Vault | 30 |
| Roadway improvements and Building Lot 635 | 35 |

## 4.4 Excavations

All excavations at the site associated with confined spaces, such as lower-building level retaining walls, must be completed in accordance with local, state, and federal requirements. Based on the Washington State Safety and Health Administration (WSHA) regulations, the advance and recessional outwash deposits and loose to medium dense weathered till soils would typically be classified as Type "C" soils. The native fine-grained deposits would be classified as Type "B" soils. The native dense to very dense unweathered till deposits would be classified as Type "A" soils.

Accordingly, temporary excavations in Type C soils should have their slopes laid back at an inclination of 1.5:1 (Horizontal: Vertical) or flatter, from the toe to the crest of the slope. Side slopes in Type B soils can be laid back at an inclination of 1:1 or flatter. Side slopes in Type A soils can be laid back at a slope inclination of 0.75:1 or flatter. For temporary excavation slopes less than 8 feet in height in Type A soils, the lower 3.5 feet can be cut to a vertical condition, with a 0.75:1 slope graded above. For temporary excavation slopes greater than 8 feet in height up to a maximum height of 12 feet, the slope above the 3.5-foot vertical portion will need to be laid back at a minimum slope inclination of 1:1. No vertical cut with a backslope immediately above is allowed for excavation depths that exceed 12 feet. In this case, a four-foot vertical cut with an equivalent horizontal bench to the cut slope toe is required.

All exposed temporary slope faces that will remain open for an extended period of time should be covered with a durable reinforced plastic membrane during construction to prevent slope raveling and rutting during periods of precipitation.

Groundwater seepage should be anticipated within excavations. We anticipate that the volume of water and rate of flow into relatively shallow excavations will be relatively minor and are not expected to impact the stability of the excavations when completed, as described. Conventional sump pumping procedures, along with a system of collection trenches, if necessary, should be capable of maintaining a relative dry excavation for construction purposes. Deeper excavations into the advance outwash formation may encounter groundwater seepage, especially near the interface with the lower fine-grained soils, with volumes and flow rates sufficient to require some level of dewatering via well points or isolated deep-pump wells.

The above information is provided solely for the benefit of the owner and other design consultants and should not be construed to imply that Terra Associates, Inc. assumes responsibility for job site safety. It is understood that job site safety is the sole responsibility of the project general contractor.

## 4.5 Foundations

The proposed buildings may be supported on conventional spread footing foundations bearing on competent native soils or on structural fill placed above the competent soils. Foundation subgrade should be prepared as recommended in Section 4.2 of this report. Perimeter foundations exposed to the weather should bear a minimum depth of one and one-half feet below final exterior grades for frost protection. Interior foundations can be constructed at any convenient depth below the floor slab.

The native silty sand soils will be easily disturbed by normal construction activity particularly when wet. Care will need to be exercised during construction to avoid excessively disturbing the subgrade. If disturbed, the material should be removed, and footings lowered to undisturbed material or grade restored with structural fill. During wet-weather conditions, to avoid disturbance, consideration should be given to protecting the fill foundation subgrade with a four-inch layer of crushed rock or lean mix concrete.

Foundations for single-family residences bearing on competent soils can be dimensioned for a net allowable bearing capacity of 2,500 pounds per square foot (psf). For short-term loads, such as wind and seismic, a one-third increase in this allowable capacity can be used. With structural loading as anticipated and this bearing stress applied, estimated total settlements are less than one-half inch.

For designing foundations to resist lateral loads, a base friction coefficient of 0.35 can be used. Passive earth pressures acting on the side of the footing and buried portion of the foundation stem wall can also be considered. We recommend calculating this lateral resistance using an equivalent fluid weight of 300 pcf. We recommend not including the upper 12 inches of soil in this computation because they can be affected by weather or disturbed by future grading activity. This value assumes the foundation will be constructed neat against competent existing fill, native soil, or backfilled with structural fill as described in Section 4.2 of this report. The values recommended include a safety factor of 1.5.

## 4.6 Slab-on-Grade Floors

Slab-on-grade floors may be supported on subgrade prepared as recommended in Section 4.2 of this report. Immediately below the floor slab, we recommend placing a four-inch-thick capillary break layer composed of clean, coarse sand or fine gravel that has less than five percent passing the No. 200 sieve. This material will reduce the potential for upward capillary movement of water through the underlying soil and subsequent wetting of the floor slab.

The capillary break layer will not prevent moisture intrusion through the slab caused by water vapor transmission. Where moisture by vapor transmission is undesirable, such as covered floor areas, a common practice is to place a durable plastic membrane on the capillary break layer and then cover the membrane with a layer of clean sand or fine gravel to protect it from damage during construction and to aid in uniform curing of the concrete slab. It should be noted, if the sand or gravel layer overlying the membrane is saturated prior to pouring the slab, it will not be effective in assisting uniform curing of the slab and can actually serve as a water supply for moisture bleeding through the slab, potentially affecting floor coverings. Therefore, in our opinion, covering the membrane with a layer of sand or gravel should be avoided if floor slab construction occurs during the wet winter months and the layer cannot be effectively drained. We recommend floor designers and contractors refer to the current American Concrete Institute (ACI) Manual of Concrete Practice for further information regarding vapor barrier installation below slab-on-grade floors.

## 4.7 Stormwater Facilities

### *Detention Vault*

We expect the bottom of the excavations for the detention vaults will expose dense to very dense till and/or medium dense outwash. Vault foundations supported by these native soils may be designed for an allowable bearing capacity of 4,000 psf. For short-term loads, such as seismic, a one-third increase in this allowable capacity can be used.

Vault walls should be designed as below-grade retaining walls. The magnitude of earth pressure development on engineered retaining walls will partly depend upon the quality of the wall backfill. We recommend placing and compacting wall backfill as structural fill as described in Section 4.2 of this report. To prevent overstressing the walls during backfilling, heavy construction machinery should not be operated within five feet of the wall. Wall backfill in this zone should be compacted with hand-operated equipment. To prevent hydrostatic pressure development, wall drainage must also be installed. A typical wall drainage detail is shown on Figure 3.

With wall backfill placed and compacted as recommended and drainage properly installed, we recommend designing unrestrained walls for an active earth pressure equivalent to a fluid weighing 35 pounds per cubic foot (pcf). For restrained walls, an additional uniform load of 100 pounds per square foot (psf) should be added to the 35 pcf. To account for typical traffic surcharge loading, the walls can be designed for an additional imaginary height of two feet (two-foot soil surcharge). For evaluation of below-grade walls under seismic loading, an additional uniform lateral pressure equivalent to 8H psf, where H is the height of the below-grade portion of the wall in feet, can be used. These values assume a horizontal backfill condition and that no other surcharge loading such as traffic, sloping embankments, or adjacent buildings will act on the wall. If such conditions will exist, then the imposed loading must be included in the wall design. Friction at the base of foundations and passive earth pressure will provide resistance to these lateral loads. Values for these parameters are given in Section 4.4 of this report.

If it is not possible to discharge collected water at the footing invert elevation, the invert elevation of the wall drainpipe could be set equivalent to the outfall invert. For any portion of the wall that falls below the invert elevation of the wall drain, an earth pressure equivalent to a fluid weighing 85 pcf should be used.

***Stormwater Ponds***

If fill berms will be constructed, the berm locations should be stripped of topsoil, duff, and soils containing organic material prior to the placement of fill. The fill berms should be constructed by placing structural fill in accordance with recommendations outlined in Section 4.2 of this report. Material used to construct pond berms should consist of predominately granular soils with a maximum size of three inches and a minimum of 20 percent fines. Terra Associates, Inc. should examine and test all onsite or imported materials proposed for use as berm fill prior to their use.

It is possible that sand and gravel soils may be exposed within the pond area. Therefore, it may be necessary to line the dead storage portion of the pond for water quality purposes depending on the final grades and exposed soils.

Due to the exposure to fluctuating stored water levels and wave action, soils exposed on the interior side slopes of the ponds may be subject to some risk of periodic shallow instability or sloughing. Establishing interior slopes at a 3:1 gradient will significantly reduce or eliminate this potential. Exterior berm slopes and interior slopes above the maximum water surface should be graded to a finished inclination no steeper than 2:1. Finished slope faces should be thoroughly compacted and vegetated to guard against erosion.

We should review the stormwater plans when they are completed and revise our recommendations, if required.

## 4.8 Infiltration Feasibility

It is our opinion that the proximity of the development to steep slopes would preclude any development of infiltration facilities or low impact development (LID) elements as the introduction of stormwater adjacent to the steep slopes has the potential to impact the stability of the slopes.

## 4.9 Drainage

***Surface***

Final exterior grades should promote free and positive drainage away from the site at all times. Water must not be allowed to pond or collect adjacent to foundations or within the immediate building areas. We recommend providing a positive drainage gradient away from the building perimeter. If this gradient cannot be provided, surface water should be collected adjacent to the structures and directed to appropriate storm facilities.

Surface water must not be allowed to flow uncontrolled over the crest of the site slopes and embankments. Surface water should be directed away from the slope crests to a point of collection and controlled discharge. If site grades do not allow for directing surface water away from slopes, then water should be collected and tightlined down the slope face in a controlled manner.

***Subsurface***

We recommend installing perimeter foundation drains adjacent to shallow foundations. The drains can be laid to grade at an invert elevation equivalent to the bottom of footing grade. The drains can consist of four-inch diameter perforated PVC pipe enveloped in washed pea gravel-sized drainage aggregate. The aggregate should extend six inches above and to the sides of the pipe. Roof and foundation drains should be tightlined separately to the storm drains. All drains should be provided with cleanouts at easily accessible locations.

## 4.10 Utilities

Utility pipes should be bedded and backfilled in accordance with American Public Works Association (APWA) or local jurisdictional requirements. At minimum, trench backfill should be placed and compacted as structural fill, as described in Section 4.2. As noted, soils excavated onsite should be suitable for use as backfill material. However, some of the site soils are fine-grained and moisture sensitive; therefore, moisture conditioning may be necessary to facilitate proper compaction. If utility construction takes place during the winter, it may be necessary to import suitable wet-weather fill for utility trench backfilling.

## 4.11 Pavements

Pavement subgrades should be prepared as described in Section 4.2 of this report. Regardless of the degree of relative compaction achieved, the subgrade must be firm and relatively unyielding before paving. The subgrade should be proof rolled with heavy rubber-tired construction equipment such as a loaded ten-yard dump truck to verify this condition.

The pavement design section is dependent upon the supporting capability of the subgrade soils and the traffic conditions to which it will be subjected. For residential access, with traffic consisting mainly of light passenger vehicles with only occasional heavy traffic, and with a stable subgrade prepared as recommended, we recommend the following pavement sections:

- Two inches of Hot Mix Asphalt (HMA) over four inches of Crushed Rock Base (CRB).
- Three and one-half inches of full depth HMA.

The paving materials used should conform to the Washington State Department of Transportation (WSDOT) specifications for half-inch class HMA and CRB.

If the existing roadway in the southern portion of the site is intended to remain without a change in alignment, we recommend a two-inch grind and overlay to improve surface conditions along the roadway.

Long-term pavement performance will depend on surface drainage. A poorly drained pavement section will be subject to premature failure as a result of surface water infiltrating into the subgrade soils and reducing their supporting capability. For optimum pavement performance, we recommend surface drainage gradients of at least two percent. Some degree of longitudinal and transverse cracking of the pavement surface should be expected over time. Regular maintenance should be planned to seal cracks when they occur.

## 5.0 ADDITIONAL SERVICES

Terra Associates, Inc. should review the final design drawings and specifications in order to verify earthwork and foundation recommendations have been properly interpreted and implemented in project design. We should also provide geotechnical service during construction to observe compliance with our design concepts, specifications, and recommendations. This will allow for design changes if subsurface conditions differ from those anticipated prior to the start of construction.

## 6.0 LIMITATIONS

We prepared this report in accordance with generally accepted geotechnical engineering practices. No other warranty, expressed or implied, is made. This report is the copyrighted property of Terra Associates, Inc. and is intended for specific application to the Arlington 360 project in Arlington, Washington and for the exclusive use of Arlington 360, LLC and their authorized representatives.

The analyses and recommendations presented in this report are based on data obtained from the subsurface explorations completed onsite. Variations in soil conditions can occur, the nature and extent of which may not become evident until construction. If variations appear evident, Terra Associates, Inc. should be requested to reevaluate the recommendations in this report prior to proceeding with construction.

## APPENDIX A

## FIELD EXPLORATION AND LABORATORY TESTING

**Arlington 360**
**Arlington, Washington**

On April 22, 2024, through April 24, 2024, we explored subsurface conditions at the site at 9 test borings advanced with a hollow-stem auger to maximum depths of approximately 50 feet below existing site grades. On April 7, 2025, through April 11, 2025, we supplement this data by drilling 6 additional wells to a maximum depth of approximately 90 feet below current site grades. The test boring locations are shown on Figure 2. The test boring locations were approximately determined in the field using GPS coordinates derived from Google Earth. The Test Boring Logs are presented on Figures A-2 and A-16.

A geotechnical engineer from our office conducted the field exploration. Our representative classified the soil conditions encountered, maintained a log of each test boring, obtained representative soil samples, and recorded water levels observed during subsurface exploration. During drilling, soil samples were obtained in general accordance with ASTM Test Designation D-1586. Using this procedure, a two-inch (outside diameter) split barrel sampler is driven into the ground 18 inches using a 140-pound hammer free falling a height of 30 inches. The number of blows required to drive the sampler 12 inches after an initial 6-inch set is referred to as the Standard Penetration Resistance value or N value. This is an index related to the consistency of cohesive soils and relative density of cohesionless materials. N values obtained for each sampling interval are recorded on the Test Boring Logs. All soil samples were visually classified in accordance with the Unified Soil Classification System (USCS) described on Figure A-1.

Representative soil samples obtained from the test borings were placed in sealed plastic bags and taken to our laboratory for further examination and testing. The moisture content of each sample was measured and is reported on the Test Boring Logs. Grain size analyses were performed on selected samples. The results of the grain size analyses are shown on Figures A-17 and A-18.

| MAJOR DIVISIONS | | | LETTER SYMBOL | TYPICAL DESCRIPTION |
|---|---|---|---|---|
| COARSE GRAINED SOILS: More than 50% material larger than No. 200 sieve size | **GRAVELS** More than 50% of coarse fraction is larger than No. 4 sieve | Clean Gravels (less than 5% fines) | GW | Well-graded gravels, gravel-sand mixtures, little or no fines. |
| | | | GP | Poorly-graded gravels, gravel-sand mixtures, little or no fines. |
| | | Gravels with fines | GM | Silty gravels, gravel-sand-silt mixtures, non-plastic fines. |
| | | | GC | Clayey gravels, gravel-sand-clay mixtures, plastic fines. |
| | **SANDS** More than 50% of coarse fraction is smaller than No. 4 sieve | Clean Sands (less than 5% fines) | SW | Well-graded sands, sands with gravel, little or no fines. |
| | | | SP | Poorly-graded sands, sands with gravel, little or no fines. |
| | | Sands with fines | SM | Silty sands, sand-silt mixtures, non-plastic fines. |
| | | | SC | Clayey sands, sand-clay mixtures, plastic fines. |
| FINE GRAINED SOILS: More than 50% material smaller than No. 200 sieve size | **SILTS AND CLAYS** Liquid Limit is less than 50% | | ML | Inorganic silts, rock flour, clayey silts with slight plasticity. |
| | | | CL | Inorganic clays of low to medium plasticity. (Lean clay) |
| | | | OL | Organic silts and organic clays of low plasticity. |
| | **SILTS AND CLAYS** Liquid Limit is greater than 50% | | MH | Inorganic silts, elastic. |
| | | | CH | Inorganic clays of high plasticity. (Fat clay) |
| | | | OH | Organic clays of high plasticity. |
| HIGHLY ORGANIC SOILS | | | PT | Peat. |

**Forest Duff - 6 inches**

**Vashon Lodgment Till**

Loose to medium dense, very moist, dark orangish brown, silty, fine SAND, trace gravel; small roots (SM).

Medium dense, moist, tan and orangish brown, silty, fine SAND, some gravel; unsorted (SM).

5

Becomes dense and brown.

Wet at 6 feet.

Becomes very dense.

Very dense, moist, gray, silty, fine SAND, some gravel; unsorted (SM).

10

Minor perched seepage 6 feet. No caving.

**Forest Duff - 6 inches**

**Vashon Advance Outwash - Olympia Sand**

Medium dense, moist, orangish brown, silty, fine SAND, some gravel (SM).

Dense, moist to very moist, grayish brown, fine SAND, some silt; beds and laminations of brown and orangish brown, silty, fine sand, trace gravel; stratified; contains mica (SP-SM).

5

Wet at 6 feet.

Becomes very dense, moist.

10

Banded oxidation.

15

Becomes trace silt.

Bed (6 inches thick) of sandy, silt; mica.

20

Minor perched seepage 6 feet. No caving.

**Forest Duff - 6 inches**

**Vashon Lodgement Till**

Medium dense, moist, orangish brown, silty, fine SAND, some gravel (SM).
Becomes mottled, orangish brown and tan; unsorted.

5

Becomes more dense and brown.

Becomes very dense. Zones of perched groundwater 6 to 7 feet.

**Vashon Advance Outwash - Olympia Sand**

Very dense, moist, grayish brown, fine SAND, some silt, trace gravel; stratified; occasional mica; beds of fine to medium sand, trace silt and silty, fine sand (SP-SM).

10

Becomes trace silt (SP).

Occasional dark gray laminations.

15

Banded oxidation.

20

Perched groundwater 6 to 7 feet. No caving.

Depth (ft) | Description | USCS

Elev.: 200 ft NAVD88

0

**Organic Topsoil - 6 inches**

**Landslide Deposits**

Loose, moist, dark brown and brown, silty, fine SAND, trace gravel (SM).

Medium stiff, moist, grayish brown and orangish brown, SILT; faint laminations; stratified; brecciated; disturbed appearance (ML).

5 Becomes stiff, silt (ML).

Becomes very stiff, brownish gray and orangish brown.

Fractured; disturbed appearance.

10

Fractured in places.

15

Stiff, moist, gray, SILT; light gray, sandy laminations (ML).

No seepage. No caving.

**Forest Duff - 6 inches**

**Landslide Deposits**

Loose to medium dense, moist, orangish brown, silty, fine SAND, some gravel; unsorted; boulders and cobbles (SM).
Becomes brown; disturbed texture; small voids in diamict.
Angular boulder (6 foot in diameter).

5

Dense, moist, brown, gravelly, fine to coarse SAND, some silt (SP-SM).

Small to medium roots.

10

Dense, moist, tan and orangish brown, silty, fine SAND, some gravel; organic inclusions; blocks of intact silt within the silty, fine sand (SM).

Wet at 12 feet.

15

**Vashon Lodgement Till**

Very dense, moist, brown, silty, fine SAND, some gravel; unsorted (SM).

**Vashon Advance Outwash - Olympia Sand**

Very dense, moist, grayish brown, fine SAND, some silt; stratified; mica (SP-SM).
Very stiff, moist, grayish brown, sandy SILT; mica (ML).

Minor perched seepage 12 feet. Minor caving 0 to 8 feet.

0

**Landslide Deposits**

Loose, moist, dark brown to black, silty, fine SAND; abundant organics; roots (SM).
Loose, moist, dark orangish brown, silty, fine SAND, trace gravel (SM).
Medium dense to dense, moist, grayish brown, interbedded silty, fine SAND and fine SAND, some silt; thinly bedded; banded oxidation; contains mica (SM).

5

Medium dense to dense, moist, grayish brown, fine SAND, some silt; stratified (SP-SM).

Bed of laminated sandy, SILT; oxidized (ML).

Bed of laminated sandy, SILT; orangish brown oxidation (ML).

10

Dense, moist to very moist, grayish brown, silty, fine SAND; faintly stratified; separated along sandy partings (SM).

Bed of laminated sandy, SILT; orangish brown oxidation (ML).

15

Minor perched seepage 1.5 to 2 feet. Moderate caving 0 to 2 feet.
No pooling at base of excavation from perched seepage above.

# Monitoring Well EB-6SI

Arlington 360 — Sheet: 2 of 2

| | | |
|---|---|---|
| Arlington, WA | Start Date: 12/12/23 | Logged By: PL |
| 20230078E001 | Ending Date: 12/12/23 | Approved By: JHS |

Driller/Equipment: Holocene Drilling/D-50/Mud Rotary
Hammer Weight/Drop: 140#/30"
Hole Diameter (in): 5
Ground Surface Elevation (ft): ≈270
Water Level Elevation (ft): 10
Groundwater Depth ATD (ft): 10

Total Depth (ft): 51.5
Well Completion Depth (ft): 50
Well Tag No.: BPX652
Top of Well Casing Elevation (ft):
Datum: NAVD 88
Groundwater Depth Post Drilling (ft) (Date): ( )

| Depth (ft) | Sample Type | Sample No. | Graphic Symbol | Description | Water Level | Blows/6" | Blows/Foot (10 20 30 40 50+) | Well Construction |
|---|---|---|---|---|---|---|---|---|
| | | | | Wet, gray to dark gray, sandy, SILT ranging to moist, gray, SILT; silt contains light gray, sandy partings; rare polished surfaces and fractures within silt (ML). | | 20 | | |
| | | | | **Olympia Fine-Grained Deposits** | | | | |
| 40 | | 9 | | Wet, dark gray, sandy, SILT; light gray sandy partings/ laminations; scattered mica; sampled using Cal-Mod (ML). | | 14 18 31 | 49 | |
| 45 | | 10 | | Moist, gray to dark gray, SILT; occasional light gray, sandy laminations; thin bed (approximately 0.25 inches thick) of dark gray, fractured silt; fractures appear to have pointed surfaces (ML). | | 13 21 33 | 54 | |
| 50 | | | | Moist, gray to dark gray, medium plasticity, cohesive, clayey, SILT; occasional light gray, sandy laminations/ partings (ML). | | | | Flat end cap |
| | | | | Groundwater encountered at 10 feet ATD. Post-drilling groundwater measurement not feasible due to mud-rotary drilling. Blow counts (Blows/Foot) from samples taken with a 2.5-inch outside diameter modified California (Cal-Mod) sampler have been adjusted to reflect standard 2-inch outside diameter SPT blow counts. | | | | |
